Autonomous Work In Motion

In this role, decisions are made on incomplete information.

We evaluate how you form beliefs, what you're uncertain about, how you validate assumptions and conclusions, how you categorize speculation, inferences, and facts, and how you make decisions.

Two Competing Working Models

The Human Validation Layer

HOW WE WORK

This role operates within the "human validation layer" framework (column on the right), not the task completion model (column on the left). There is no cycle of receiving a brief, producing an output, submitting it, and waiting for approval.

That workflow produces deliverables, not thinking. In this environment, unverified output is worse than no output at all.

Observe a signal. The work begins when something in the data, the product, or the market catches your attention. Not when someone assigns you a task. You notice a pattern, an anomaly, a gap, or a contradiction. The observation is yours. It is not prompted by a ticket, a brief, or a directive. The ability to see what matters before being told to look is the starting point of everything we build.

Question the signal. Before acting on what you observed, you interrogate it. Is this real? What assumptions am I making? What would need to be true for this signal to matter, and what would make it meaningless? This is where most people skip ahead. They see something interesting and start building. We do not. We pressure-test the observation before committing resources to it. If the signal does not survive scrutiny, it was not a signal. It was noise.

Form a hypothesis. Once the signal survives questioning, you state what you believe and why. You name the constraints. You define what would prove you wrong. This is not a plan. It is a falsifiable position. The hypothesis makes your thinking visible and your assumptions explicit. If you cannot name what would change your mind, you do not have a hypothesis. You have an opinion.

Build and test. This is where AI tools become powerful. Use them aggressively. Build fast. Generate code, prototype interfaces, construct pipelines. But after the build, interrogate the output. Does it hold? Where does it break? Does the system you built actually support the hypothesis you formed, or did the AI produce something that looks right but rests on assumptions you never verified? The build is not the end of the work. It is the beginning of the verification.

Validate before shipping. Before anything reaches a client, a stakeholder, or a production system, check your assumptions against reality one more time. Did the data support what you claimed? Did the system perform as documented? Are there gaps you glossed over because the output looked clean? If the evidence demands that you update your beliefs, update them. Then ship. Shipping something you have validated is confidence. Shipping something you have not validated is negligence.

The feedback loop between validation and questioning is continuous. Beliefs update as evidence accumulates. A conclusion you were confident about on Tuesday may need revision by Thursday because new data arrived. That revision is not a failure. It is the process working correctly. Refusing to revise when the evidence demands it is the failure.

SIDE-BY-SIDE COMPARISON

Dimension	Task Completion Model	How We Work
Goal	Deliver output	Establish truth
Starting point	Task or directive	Observation from reality

Role of AI	Primary thinker	Support tool
Feedback loop	Revise output	Update beliefs
Success criteria	Accepted deliverable	Verified correctness
Speed	Fast	Slower upfront, rarely wrong
Risk	Hidden errors shipped confidently	Slower iteration cycles

FAILURE MODES

Task completion model: Something looks right, gets accepted, and is wrong underneath. The error is invisible until a client acts on it. By then the damage is done and the rework cost is ten times what verification would have cost upfront.

How we work: Too slow or over-analysis. But rarely wrong. We accept slower iteration as the cost of verified correctness. That tradeoff is deliberate.

WHAT THIS IS NOT

This is not a role where you receive instructions, prompt an AI tool, and deliver the output. That model produces work that looks correct on the surface but has no human verification layer underneath it. In a high-stakes environment where clients make decisions based on what we produce, the verification layer is the entire value of the role. Without it, the output is decoration.

This is not a role where speed of delivery replaces depth of thought. Fast output built on unverified assumptions creates more damage than slow output built on tested foundations. We value velocity, but velocity without validation is recklessness.

This is not a role where AI does the thinking and you manage the delivery. AI is a tool. It generates, retrieves, structures, and builds. It does not question its own assumptions. It does not know when its output is wrong. It does not update its beliefs when reality contradicts them. Those are human responsibilities. They cannot be delegated.

HOW YOUR WORK WILL BE EVALUATED

Your submissions must make your thinking visible.

You are expected to explicitly show: what you observed vs what you assumed, what you believe vs what you verified, what could be wrong and why, and what would change your conclusion.

If your work reads as a clean, fully structured output with no visible reasoning, uncertainty, or validation, it will be treated as incomplete and will not be evaluated.

WHAT WE HIRE FOR

We are hiring for the reasoning that happens between the steps. The moment after you observe a signal where you decide whether to trust it. The moment after AI generates an output where you decide whether to verify it. The moment after you form a conclusion where you ask yourself what would make it wrong. Those moments are invisible in a deliverable. They are visible in the quality of the thinking behind it.

AI builds. You think. The thinking is what we hire for.
